

Leading-parton-cut control: ratios

Four-state slepton–bino $150/140\text{ GeV} \cdot \sqrt{s} = 13\text{ TeV} \cdot$ nominal 60k vs lower-cut 20k original events

Thick: conditional fixed-N. Thin: conditional + independent integration. Grey band: [0.90, 1.10].

An interval must lie wholly inside the band; a central ratio alone is insufficient. x / text: precision unresolved.

Cutoff-control approximation (leading parton 50 to 20 GeV). Unknown integration-selection covariance; no calibrated correction.
